Keywords:	Elections, Public Opinion, and Voting Behavior, Party Competition, Policy Issues, Twitter
Abstract:	The issue yield model introduced a theory of the heresthetic use of policy issues as strategic resources in multidimensional party competition. We extend the model by systematically addressing the specificities of issue yield dynamics in multi-party systems, with special regard to parties' issue yield rankings (relative position) and issue yield heterogeneity (differentiation) on each issue. Secondly, we introduce a novel research design for original data collection that allows for a more systematic testing of the model, by featuring: a) a large number of policy issues; b) the use of Twitter content for coding parties' issue emphasis; c) an appropriate time sequence for measuring issue yield configurations and issue emphasis. We finally present findings from a pilot implementation of such design, performed at the occasion of the 2014 European Parliament election in Italy. Findings confirm the soundness of the design and provide support for the newly introduced hypotheses about multi-party competition.

Issue yield and party strategy in multi-party competition

ABSTRACT

The issue yield model introduced a theory of the herestethic use of policy issues as strategic resources in multidimensional party competition. We extend the model by systematically addressing the specificities of issue yield dynamics in multi-party systems, with special regard to parties' issue yield rankings (relative position) and issue yield heterogeneity (differentiation) on each issue. Secondly, we introduce a novel research design for original data collection that allows for a more systematic testing of the model, by featuring: a) a large number of policy issues; b) the use of Twitter content for coding parties' issue emphasis; c) an appropriate time sequence for measuring issue yield configurations and issue emphasis. We finally present findings from a pilot implementation of such design, performed at the occasion of the 2014 European Parliament election in Italy. Findings confirm the soundness of the design and provide support for the newly introduced hypotheses about multi-party competition.

Introduction

According to a growing body of literature, the dynamics and strategies of party competition have seen a gradual but steady change in recent decades. A number of studies have shown the increasing importance of the *political issues of the day* for voting behaviour, on both sides of the Atlantic (Page & Brody, 1972; Pomper, 1972; Miller, Miller, Raine, & Brown, 1976; Nie, Verba, & Petrocik, 1976; Carmines & Stimson, 1980; Franklin, 1985;

1
2
3 Franklin, Mackie, & Valen, 1992; Alvarez & Nagler, 1995, 1998; Borre, 2001; Heath, Jowell,
4 & Curtice, 2001; Aardal & van Wijnen, 2005). At the same time, recent studies have clearly
5 documented how parties have reacted to such changes, with their platforms dedicating more
6 space to a wider variety of issues unrelated to traditional dimensions of party competition
7 (Green-Pedersen, 2007). These dynamics appear relevant, as recent elections have shown
8 increasing success of new, non-mainstream parties often focusing on a narrow range of issues
9 (Hobolt & De Vries, 2015).

16
17

18 What has been missing so far, however, is a general, comprehensive theoretical model of
19 the *issue selection process*, i.e. of *what* issues should be emphasized by a party in a campaign.
20 Previous studies have shown that parties are in part responsive to a general party system
21 agenda (McCombs & Shaw, 1972; Nannestad & Paldam, 1997; Steenbergen & Scott, 2004;
22 Wagner, 2012), and in part focusing on issues they are known to *own* (Petrocik, 1996).
23 However, no perspective to our knowledge has systematically and empirically investigated
24 the underlying (and perhaps causally antecedent) process through which parties *strategically*
25 select issues to be emphasized, e.g. according to *heresthetics* concerns such as those theorized
26 by William Riker (1986).

37

38 Recently, a solution to fill this gap has been introduced through the *issue yield* model (De
39 Sio & Weber, 2014). This model posits that parties select campaign issues based on two
40 strategic considerations: a) whether a policy position on the issue is positively associated with
41 the party (in both substantive and statistical sense); b) whether such position is also widely
42 shared in the general electorate. If both conditions are met, that issue will allow the party to
43 reach out to a larger voter base. The model then develops an empirical strategy, by computing
44 – from simple survey questions – an *issue yield* index expressing the electoral potential
45 offered by each issue to each party. The main testable implication of the model is that parties
46 will give more emphasis to those issues that present a higher yield.

3 The model has been mostly tested so far on comparative data on EU party systems, by
4 relying on Manifesto data for issue emphasis and European Election Studies data for public
5 opinion (De Sio & Weber, 2014; De Sio, Franklin, & Weber, 2016). Thus, all such
6 applications are secondary analyses, relying on data collection processes that were not
7 designed with such theory in mind. This choice is not optimal, in terms of: a) the usually
8 small number of issues covered; b) the adequacy of Manifesto data for testing the model's
9 hypotheses; c) the appropriateness of the time sequence in the collection of data for
10 constructing the independent and dependent variables. Moreover, the above applications have
11 considered the specific dynamics of multi-party competition only to a limited extent.

22
23 In this paper we present – and apply empirically – a theoretical development of issue yield
24 theory towards multi-party competition, along with a novel research design aimed at
25 addressing the aforementioned concerns, thus allowing more rigorous empirical testing. Such
26 design is based on the following components: (a) a pre-electoral selection of a large number
27 of potentially relevant issues; (b) a voter survey, whose questionnaire includes items for all
28 the aforementioned issues, aimed at capturing issue yield configurations for each party before
29 the campaign; (c) the collection and coding of Twitter content for each party during the
30 campaign (according to a coding scheme covering exactly the same issues identified in step
31 (a)), in order to properly capture the strategic campaign choices by political parties. As a pilot
32 study, we fielded such design at the occasion of the campaign for the European Parliament
33 elections of 2014 in Italy.

8 **Party strategy and issue yield: a perspective for multi-party** 9 **systems** 10

11
12
13
14 The dynamics that govern the selection by political parties of those issues that make up their
15
16 agendas and campaigns lie at the core of the process of representation, and they present a
17
18 direct relationship to party competition. This is already visible in early models of party
19
20 competition (Downs 1957) where the fundamental interaction between parties and voters that
21
22 governs electoral competition takes place through a shared language (cf. Fuchs &
23
24 Klingemann, 1989) structured around policy issues. It is on such issues that voters assess
25
26 party platforms, and it is on such issues that parties adapt themselves to fit voters' preference
27
28 distributions. According to Downs, such issue language is simplified in terms of a *single*
29
30 *dimension of conflict*, which – under additional assumptions – allows the emergence of a
31
32 Nash equilibrium, implicitly pushing parties towards the position of the *median voter* under
33
34 certain political circumstances. The strategic virtue of such median position is that it
35
36 effectively accommodates two goals of parties: expanding their voter base, while retaining as
37
38 possible their extant support.
39
40
41
42

43
44 However, such conception has been also challenged, with the notable example of the
45
46 *valence politics* framework (Stokes 1963) where the same goal – expanding the electoral base
47
48 while not jeopardizing extant support – is reached through very different means. Instead of
49
50 focusing on *divisive* issues (issues where a distribution of voter preferences exists, and where
51
52 parties employ a *positional* strategy), a party can selectively focus on few widely shared, non-
53
54 divisive goals (historical examples are related to national security, corruption and economic
55
56 prosperity), where it can claim superior competence and credibility.
57
58
59
60

1
2
3 The two models differ in a variety of aspects. However, from our point of view there is one
4 aspect (overlooked by most literature) that is mostly distinctive between the two approaches,
5 and which highlights the importance of political agendas. It is clear in Stokes' contribution
6 that the issue agenda is not considered fixed, and is instead considered as a *strategic resource*,
7 which parties have an interest in *dynamically* manipulating to their convenience.¹
8
9

10
11
12
13
14 Such intuition was not followed by a systematic theoretical development before the
15 introduction of the idea of *heresthetics* by Riker (1986). According to Riker's intuition,
16 parties in an unfavourable position on the main dimension of conflict (often, the left-right
17 dimension) will concentrate their emphasis and attempt to turn the campaign debate on other
18 issues where they enjoy a more favourable position.
19
20
21
22
23

24
25 The introduction of this approach raises then a key question: what are such "most
26 favourable issues" for each party? Can a general model be proposed, capturing the incentives
27 and disincentives that each issue offers to each party?² This question has received uneven
28 attention from the literature, so that we might say that no theoretical framework (with a
29 convincing empirical operationalization) has so far filled this gap. Obvious seminal
30 contributions in this direction can be identified in *saliency theory* (Budge & Farlie, 1983) and
31 *issue ownership* (Petrocik, 1996). However, the former saw the *selective issue emphasis*
32 adopted by political parties mostly as a communication tool for presenting the relatively static
33 *ideological* stances of the party (Budge, 2015); and the latter, too, assumed relatively static,
34 long-standing reputations of competence on specific issues. As a result, both approaches are
35 not compatible with the aforementioned dynamic, strategic view of party agendas; a view
36 which appears more and more appropriate, especially with the increasing volatility and
37 tensions characterizing multi-party systems in Western Europe (Chiaramonte & Emanuele,
38 2015; Hernández & Kriesi, 2016).³ Recently, a more dynamic view of the strategic use of
39 issue emphasis has been introduced with the notion of *issue entrepreneurship* (Hobolt & De
40
41
42
43
44
45
46
47
48

52
53
54
55
56
57
58
59
60

1
2
3 Vries, 2015); however, this concept is circumscribed by its proponents⁴ to what other authors
4
5 have identified as *niche* parties (Meguid, 2008), and cannot be easily generalized to all
6
7 (including mainstream) parties (Hobolt & De Vries, 2015, pp. 1162–1165).
8

9
10 Following a somehow different path (relying on a dynamic, survey-based measurement of
11
12 different distributions of preferences), the *issue yield* model has proposed a generalized model
13
14 explicitly aimed at *positional* issues, which directly confronts the question of assessing the
15
16 risk-opportunity configuration offered by each issue to each party, without being limited to
17
18 new issues or specific types of parties. Let us see this contribution in more detail.
19

20 21 Issue yield

22
23
24 The recently introduced *issue yield* model (De Sio and Weber 2014) has been presented as a
25
26 model of *strategic issue selection* by political parties. The model addresses this question in
27
28 two steps: 1) it theoretically identifies two criteria that parties can use to assess the electoral
29
30 risks and opportunities associated with each issue; 2) it develops a synthetic index based on a
31
32 combination of such criteria.⁵ In a nutshell, optimal issues are those where a policy position⁶
33
34 is: a) *associated with the party* (both in statistical and substantive sense), so as to provide a
35
36 beneficial competitive linkage for the party and minimize the risk of internal divisions; b)
37
38 *widely supported in the general electorate* (well beyond the current level of party support), so
39
40 as to offer a potential for electoral expansion (De Sio, 2010; De Sio & Weber, 2014). Finally,
41
42 the model defines as *bridge issues* those issues that combine both characteristics (as they in
43
44 fact represent a “bridge” allowing the party to reach out to a new, larger voter base) and
45
46 predicts that such issues will receive the highest emphasis in party campaigns.
47
48
49

50
51 To help grasping the key mechanisms of the model, we present in Table 1 a summarization
52
53 of the electoral opportunities and risks presented by different issues to the four major Italian
54
55 parties, according to an original CAWI survey we administered in Spring 2014, during the
56
57
58
59
60

1
2
3 European parliament election campaign (see below). For each policy statement, we report: a)
4 the percentage of agreement among *all respondents*; b) the percentage of agreement *among*
5 *voters of each of the parties*;⁷ c) values of the *issue yield* index offered by each issue
6
7
8
9
10 (separately for the *pro* and *anti* side) to each party.⁸

11
12
13
14 Table 1 about here
15
16
17

18
19 As clear from the table, values of the issue yield index offer a summarization of a positive
20 combination of *high support in general* and *even higher support within the party* (implying a
21 positive party-issue association). This can be effectively exemplified by contrasting the issue
22 yield configurations for the centre-left, mainstream Democratic Party (PD) and for the right-
23 wing, populist Northern League (Ln). Issues with the highest yield for the PD are (ranked by
24 decreasing yield): 1) support for sustainable development (0.89); 2) support for a budget
25 reduction for F-35 fighter-bombers (0.88); 3) support for reduction of income inequality
26 (0.85) and 4) for EU integration (0.85); 5) hostility towards allowing macro-regions to secede
27 from Italy (0.84 for the *anti* position, in the penultimate row of the table). As an example, the
28 high value of the index for sustainable development (0.89) reflects the high support in the
29 general electorate (87 %) and an even higher support within the party (93 %). As a result,
30 such issue does not present risks of internal division, and offers large opportunities for
31 potential electoral expansion.
32
33
34
35
36
37
38
39
40
41
42
43
44
45
46

47 Similar considerations apply for the Northern League. Its configuration shows, as top
48 issues: 1) support for a tougher attitude against India in the *Enrica Lexie* case (0.98); 2)
49 support for more restrictive laws against immigration (0.95); 3) support for privileging
50 Italians in welfare access (0.93); 4) support for the legalization of prostitution (0.82) and 5)
51 for a budget reduction for F-35 fighter-bombers (0.82). In the case of the *Enrica Lexie* issue,
52
53
54
55
56
57
58
59
60

1
2
3 the value of 0.98 reflects the high support in the general electorate (80 %) and the almost
4
5 unanimous support within the party (98 %). In general, it is clear that lower-yield issues, for
6
7 each party, are associated with lower levels of general support and higher risks of internal
8
9 divisions.
10

11 As a result, we argue that the issue yield model offers an effective way to assess the
12
13 combination of risks and opportunities that each issue offers to each party. As such, it offers a
14
15 model of strategic issue selection that is not constrained to specific (types of) parties.
16
17 However, further elaboration is needed, in terms of the complex issue yield dynamics of
18
19 multi-party systems. This is the task we now confront in our original elaboration.
20
21
22
23
24
25

26 Issue yield dynamics in multi-party systems

27

28
29 The patterns shown in Table 1 already suggest how multi-party competition presents issue
30
31 competition dynamics that differ from a two-party context. In a two-party system, an issue
32
33 with a high yield for a party will likely present a much lower yield for its rival: as a result, the
34
35 two will mostly emphasize different issues. In a multiparty system the situation is more
36
37 complex: in particular, it is likely that e.g. two parties will have a high yield on the same
38
39 issue. In principle, we would expect both parties to emphasize it; in practice, however, both
40
41 parties will carefully assess whether to use the issue or not, to avoid the risk that bringing the
42
43 issue to the attention of voters might, in the end, favour the *other* party.
44
45

46 This problem cannot be directly addressed by the issue yield index alone, as it only takes
47
48 into account one party at a time. In order to account for multiparty dynamics, we suggest to
49
50 introduce two additional aspects that concern respectively: a) the *relative position* of a party –
51
52 in terms of yield on a specific issue – vis-à-vis other parties; b) the extent of *issue yield*
53
54 *differentiation* among parties within the same issue.
55
56
57
58
59
60

1
2
3 Regarding the first aspect, we argue that having a relatively high yield on an issue might
4
5 still not be enough for a party to be motivated in strategically emphasizing that issue. A party
6
7 also has to take into account its *relative position* vis-à-vis other parties. Having a relatively
8
9 high yield might still be compatible with the presence of another party with an even *higher*
10
11 yield. In this scenario the issue yield mechanism might be dampened, as the party would
12
13 avoid emphasizing the issue, given that such emphasis might result in an electoral benefit for
14
15 *another* party. As a result, we argue that – for a party – the issue yield mechanism will act in
16
17 full force only for such issues where the party enjoys a favourable relative position (i.e. with
18
19 the highest ranking yield on that issue). Therefore, the higher the relative position of a party
20
21 on an issue, the higher the impact of issue yield.
22
23

24
25 As for the second aspect, it should be clear enough by comparing – in Table 1 – issue yield
26
27 values for the *ius soli* issue (granting Italian citizenship to all babies born on Italian soil). The
28
29 issue yield configuration appears clearly differentiated on this issue, ranging from a low 0.34
30
31 for Ln to a very high 0.82 for the PD, and with clearly separated intermediate values of 0.54
32
33 for Fi and 0.67 for M5S. In such a scenario, we would expect issue emphasis to reflect closely
34
35 issue yield, with the PD likely emphasizing the issue and other parties presenting lower levels
36
37 of emphasis. On the contrary, consider an issue such as heterologous insemination. Here
38
39 values of yield for all parties are in a much narrower range (between 0.57 and 0.70): as a
40
41 result, there is a high risk that – if one party attempts to move the public debate towards this
42
43 issue – this effort might either raise an inconclusive discussion among different parties – none
44
45 of which enjoys some particularly beneficial position (not even the one raising the issue) – or
46
47 become counterproductive by increasing the perceived importance of an issue on which other
48
49 parties could potentially intercept the support with more convincing arguments during the
50
51 campaign (given that the baseline levels are close). In this case, we expect parties to avoid
52
53 wasting campaign energies on such unproductive or potentially damaging issues, leading to a
54
55
56
57
58
59
60

1
2
3 *lower importance* of the logic of issue yield. Conversely, and in general terms, the higher the
4
5 issue yield differentiation among parties on a given issue, the higher the impact of issue yield.
6
7

8 Hypotheses 9

10
11 We finally express the aforementioned considerations in terms of empirical hypotheses.
12
13 We anticipate here that (as discussed in the next section) the case study concerns the
14
15 campaign for the European Parliament 2014 election in Italy, and that the parties' strategic
16
17 issue emphasis will be measured through a coding of Twitter content. In light of these
18
19 choices, our research questions translate into the following hypotheses:
20
21

22 H1: *issue yield* (measured pre-campaign) predicts Twitter emphasis in the campaign;
23

24 H2: *issue yield* presents a positive interaction with the party's *relative position* (in terms of
25
26 issue yield) on a given issue;
27

28
29 H3: *issue yield* presents a positive interaction with *issue yield differentiation* on a given
30
31 issue.
32

33 34 **Capturing party strategy: a novel research design** 35

36
37 As anticipated in the Introduction, several contributions have empirically tested the theoretical
38
39 predictions of the issue yield model. All of them have employed secondary analysis, thus
40
41 relying on existing datasets whose data collection process was not designed with issue yield
42
43 theory in mind. Thus, we argue that a newly conceived research design aimed at testing issue
44
45 yield theory might improve the data collection process in the following directions:
46
47

48 a) Scope and number of issues. So far, applications of the issue yield model have been
49
50 relying, for calculating issue yield configurations, on the European Election Study Voter
51
52 Component of 2009 and 2014 (De Sio & Weber, 2014; De Sio, Franklin, & Weber, 2016).
53
54 Such surveys only included a relatively small number of policy issue statements (12 for the
55
56 EES 2009, 8 for the EES 2014), mostly aimed at capturing general orientations on broader
57
58
59
60

1
2
3 value dimensions (economic, cultural, EU integration) than current, salient, country-specific
4
5 campaign issues. As a result, an original research design should aim at including a larger
6
7 number of policy issues, ideally covering most of the questions that are salient in the political
8
9 debate in a given country (as they would become the strategic resources employed by parties
10
11 during the campaign).
12

13
14 b) Operationalization of the dependent variable. The aforementioned applications have
15
16 operationalized party emphasis on different issues through Manifesto data. This poses at least
17
18 two concerns. First, in general party manifestos are actually recognised to not fully represent
19
20 the *strategic* communication employed by parties for electoral purposes. Not only manifestos
21
22 inevitably reflect the compromises related to intra-party conflicts (and the need to
23
24 accommodate the requests of party ideologists), but – most importantly – they inherently run
25
26 in a logic that is much different compared to the issue yield model. While the model posits
27
28 that parties will focus on a relatively small number of strategic issues, party manifestos aim at
29
30 covering many issues across different policy domains, in order to supply members and
31
32 militants with the official position of the party. This logic is not fully compatible with the
33
34 kind of strategic emphasis described by the issue yield model. Second, Manifesto data
35
36 introduce an additional difficulty. Issue yield configurations (the main predictor) are
37
38 measured by assessing public opinion on specific policy statements, while issue emphasis (the
39
40 outcome) is measured as the proportion of a party manifesto that is devoted to a particular
41
42 content *category*. Such categories are relatively broad, and with no specific connection to
43
44 actual survey statements. As a result, a stage of *conceptual matching*, assessing which
45
46 Manifesto category can be associated with a survey statement, is required. Such process
47
48 yields matchings of variable quality: while some statements very closely match a Manifesto
49
50 category, some often do not.
51
52
53
54
55
56
57
58
59
60

1
2
3 c) Time sequence of data collection. Issue yield studies so far have mostly computed the
4 main predictor (issue yield) from *post-electoral* surveys, and the outcome (issue emphasis)
5 from *pre-electoral* manifestos. Such studies have properly acknowledged this paradox,
6 preventing any causal interpretation, and arguing that in fact both measures were capturing
7 the effect of *latent* issue yield configurations; however, a proper design should attempt at
8 measuring the predictor and the outcome by collecting data with an appropriate time
9 sequence.
10
11
12
13
14
15
16
17

18 In light of these concerns, we developed a novel research design. Among others, the main
19 distinguishing feature of the design is in the selection of Twitter content to capture the
20 strategic communication choices performed by political parties. Among the possible
21 alternatives for capturing parties' strategic issue emphasis choices, social media represent
22 nowadays an interesting possibility. In a way, they represent perhaps the most widely
23 accessible form of party communication, with party leaders increasingly aware of their power.
24
25
26
27
28
29
30
31

32 There are good reasons why party communication on Twitter might follow strategic
33 considerations, much more than Manifesto data: given the much higher temporal adaptability
34 and interaction potential of Twitter content (compared to party manifestos) for shaping the
35 actual electoral campaign (Graham, Broersma, Hazelhoff, & Haar, 2013), we expect a party to
36 see Twitter as an ideal tool to emphasize the issues presenting the highest electoral potential.
37
38
39
40
41
42

43 This is not only due to the potential for *direct* party-voter interaction on the social media,
44 but – perhaps most importantly – to a potential for *indirect* interaction, deriving from the
45 systematic use that journalists (and other politicians) make of the official Twitter accounts of
46 political parties and leaders to learn about their political messages, or for directly broadcasting
47 politicians' tweets to a much wider and more traditional audience. As a consequence, Twitter
48 is also increasingly attracting the interest of political behaviour scholars (Barberá, 2015;
49 Dubois & Gaffney, 2014; Vaccari et al., 2013). Therefore we argue that the content diffused
50
51
52
53
54
55
56
57
58
59
60

1
2
3 through political parties' Twitter accounts might be effectively used to capture their strategic
4 political communication. However, our choice is conditional on a necessary theoretical
5 assumption, which we label as the *press-release assumption*: regardless of how many
6 followers (and of which type) a party's Twitter account might have, and regardless of how
7 unrepresentative and elitist the Twitter audience might be in a given country, we assume that
8 parties will use Twitter anyway to communicate their desired messages to the media, just like
9 in a press release; the appropriateness of this assumption appears well supported by previous
10 empirical research (Parmelee & Bichard, 2011; Verweij, 2012; Parmelee, 2013; Kreiss, 2016).
11 As a result, we deem party communication on Twitter a valid indicator of their actual strategic
12 priorities.
13
14

15
16
17
18
19
20
21
22
23
24
25 Indeed, this identifies party communication on Twitter as a privileged field to test the
26 predictions of issue yield theory: while party manifestos represent an excellent source to
27 measure the underlying ideological stances, they may not fully capture short-term strategic
28 emphases that characterize contemporary campaigns. Also, while manifestos often contain
29 compromise choices related e.g. to different groups within a party, Twitter can be expected to
30 effectively capture the genuinely strategic component of party communication (Nooy &
31 Kleinnijenhuis, 2013; Shaw, 2006).
32
33
34
35
36
37
38
39

40
41 As a result, the newly proposed research design – aimed at addressing the above concerns
42 – features three main stages.
43
44

- 45 (a) a pre-electoral selection of a large number of potentially relevant issues. This
46 should ideally be performed without constraints on the number of issues, and with the
47 purpose of covering all issues that might potentially be employed during the coming
48 campaign;
49
50 (b) a voter survey, based on a questionnaire including items for all the previously
51 identified issues, aimed at capturing the issue yield configurations for each party
52
53
54
55
56
57
58
59
60

1
2
3 before the campaign. The collected data should allow to compute the main predictor,
4 the issue yield of each positional issue for each party (issue yield calculation only
5 requires a positional item for each issue, and a separate item for party preference);
6
7

8
9 (c) the collection and coding of Twitter content for each party during the campaign
10 (according to a coding scheme covering exactly the same issues identified in step (a)),
11 in order to properly capture the strategic campaign choices by political parties. Ideally,
12 tweets should be separately coded by at least two independent coders, in order to
13 assess inter-coder reliability of the coding scheme. The coding procedure requires
14 coders to assign each tweet either to one of the previously identified issues, or to a
15 residual “other issue” category, or to a “non-issue content” category.
16
17
18
19
20
21
22
23
24
25
26

27 A data collection process performed according to the aforementioned stages allows, in our
28 view, a more rigorous empirical assessment of the theoretical predictions formulated by the
29 issue yield model.
30
31
32

33 A pilot study

34
35 We proceeded to implement a pilot study for this research design, at the occasion of the 2014
36 EP elections in Italy.⁹ As a preliminary assessment of the relevance of Twitter communication
37 in Italy (at least in terms of the validity of the *press-release assumption*), we report that the
38 number of Italian Twitter users reached 8.9 million in December 2014. All Italian political
39 parties and party leaders make a systematic use of Twitter accounts at campaign time, and the
40 media comment on political leaders’ tweets on a daily basis.
41
42
43
44
45
46
47
48
49
50

51 The first stage (issue identification) led our team to identify 23 positional statements,
52 ranging from economic issues (tax evasion, income inequality, unemployment benefits) to
53 social issues (civil partnerships, abortion) to issues specifically related to the European Union
54
55
56
57
58
59
60

1
2
3 (EU integration, Euro). Actual question wordings for all issues can be found in Table A1 in
4
5 the Appendix.¹⁰
6

7
8 Second, we fielded the questionnaire through a pre-electoral CAWI (Computer Assisted
9
10 Web Interviewing) survey (N = 1608).¹¹ The data collected allowed us to compute the main
11
12 predictor, the issue yield of each positional issue for each party (8 parties and 23 issues for a
13
14 total of 184 observations¹²), at the correct point in time, i.e. based on *pre-electoral* data. As
15
16 previously stated, such yield is hypothesized to predict Twitter emphasis on the same issues.
17

18
19 Third, we collected all tweets for the official accounts of the main Italian parties and their
20
21 leaders¹³ during a campaign window of 21 days.¹⁴ Then, all tweets were manually coded by
22
23 two independent coders, required to assign each tweet to one of the aforementioned issues, or
24
25 to classify them as either dedicated to other issues or to non-issue content. As reported in
26
27 Table 2, Cohen's Kappa statistic, measuring inter-rater agreement, gives a value of 0.80.¹⁵
28
29 After checking inter-rater agreement, one of the two coders was preferred for the slightly
30
31 higher number of tweets classified as issue content. Such classification of tweets has allowed
32
33 the final computation of the outcome, i.e. parties' Twitter emphasis on each issue.
34
35
36
37

38 Table 2 about here
39
40
41
42

43
44 Our pilot implementation of the proposed research design allowed, in our view, to address
45
46 the concerns expressed at the beginning of this section. First, we were free to include a
47
48 relatively large number of issues, in fact covering all the main issues that parties would later
49
50 employ in the campaign. Secondly, the manual coding procedure benefited substantially from
51
52 the lack of a *conceptual matching* stage: the guide for coders was not represented by general
53
54 category coding guidelines to be then linked to survey statements (such as when using
55
56 Manifesto data) but by the survey statements themselves. Finally, the measurement of issue
57
58
59
60

1
2
3 yield configurations in pre-electoral data goes in the direction of addressing the above concern
4
5 related to the time sequence of the data collection. The data collection process we achieved is
6
7 not a full implementation of the research design, as the timeframes of both the predictor and
8
9 the outcome are still in fact coincident; however, this already represents a substantial
10
11 improvement compared to previous applications, where data for the outcome were collected
12
13 *before* data for the predictor.
14
15

16 17 **Modelling choices and statistical issues** 18

19
20 In addition to the general characteristics of the research design, there are few additional
21
22 technical considerations related to the operationalization of specific indicators, as well as the
23
24 choice of an appropriate statistical method for model testing.
25
26

27 28 **Modelling multiparty competition** 29

30
31 As anticipated in the theoretical section, interparty influences on political communication can
32
33 be described in terms of the *relative position* of a party – in terms of issue yield – on a given
34
35 issue and of the *issue yield differentiation* on a given issue. The relative position of political
36
37 parties in terms of issue yield is operationalized by rescaling – within each issue, for all
38
39 parties – the yield to vary between 0 and 1, where 0 is assigned to the minimum observed
40
41 level of issue yield on that specific issue, 1 to the maximum observed value, and all
42
43 intermediate values rescaled accordingly to intermediate values. As a result, the party with the
44
45 highest yield on an issue will score 1, the party with the lowest yield will score 0, and other
46
47 parties will score intermediate values. This effectively captures the relative issue yield
48
49 position of the party on each issue.¹⁶ Issue yield differentiation is instead operationalized by
50
51 looking – for each issue – at the *range* between the maximum and the minimum issue yield
52
53 values registered for different political parties on the same issue. Figure A1 in the Appendix
54
55 presents the distribution of this issue-level indicator.
56
57
58
59
60

1
2
3 Therefore, we model the emphasis assigned by political parties to issues as depending on
4 issue yield, our main predictor, as well as by its interaction with the two aforementioned
5 aspects of multiparty competition. In particular, we expect both the interaction coefficients
6 between the multiparty competition variables and the *yield* variable to be positive: on the one
7 hand, we expect political parties who are higher in the ranking of issue yields to display a
8 stronger effect of issue yields on issue emphasis. In fact, having the greatest yield on a certain
9 issue implies that the party is very strongly associated with the issue, and thus the return for
10 emphasizing it will be higher than for other parties.
11
12
13
14
15
16
17
18
19

20
21 On the other hand, a greater range between the minimum and maximum issue yield implies
22 that the specific issue is less competitive (some parties will clearly avoid the issue), and again
23 the parties with the higher yield are more clearly advantaged by its emphasis. When such
24 range is smaller, it means that the highest and lowest issue yields are closer to each other, and
25 therefore emphasizing that issue might not result in a productive strategy for political
26 parties.¹⁷
27
28
29
30
31
32
33
34

35 Twitter emphasis as censored data

36
37 Are political parties' tweets resulting from strategic computations that can be predicted by the
38 issue yield model or, rather, do they represent erratic expressions detached from the
39 underlying dynamics in public opinion? Different answers to this question have important
40 implications for correctly modelling our dependent variable, and this requires few additional
41 considerations.
42
43
44
45
46
47

48
49 In the first place, issue emphasis in our study is measured by the proportion of tweets that
50 have been assigned to issue categories. This implies that the dependent variable represents a
51 proportion: as a result, it is constrained between 0 and 1. Moreover, the distribution of tweets
52 is strongly asymmetrical, with a large majority of party-issue combinations (71.2 %)
53
54
55
56
57
58
59
60

1
2
3 presenting no tweets at all (see Figure A2 in the Appendix).¹⁸, In this case, predictions from a
4
5 linear model are likely to fall outside of the zero threshold, producing logically impossible
6
7 expectations of negative emphasis. This will also decrease variance, as values of the
8
9 dependent variable approach 0, leading to an underestimation of the uncertainty in our
10
11 inferences. For all these reasons, OLS regression might not be appropriate. We chose then to
12
13 treat the proportions as a distribution censored in 0.¹⁹ This corresponds to the idea that parties
14
15 would decrease emphasis even below zero, if that would be possible, for issues that are really
16
17 unfavourable; while, in principle, some issues would receive an actual zero emphasis as they
18
19 are simply not considered very relevant to be mentioned. As a result, the dependent variable
20
21 might be considered (following previous applications) as censored at 0, thus leading to the
22
23 choice of a Tobit model, which we adopt for our analysis. As a result, the estimated Tobit
24
25 model is the following:
26
27
28
29
30
31

$$Emph_{ij} = \alpha + \beta Yield_{ij} + \gamma Yield_{ij} \cdot Rel_{ij} + \delta Yield_{ij} \cdot Diff_j + \theta X + \varepsilon_{ij} \quad (1)$$

$$Emph_{ij} = \begin{cases} y_{ij}^* & \text{if } y_{ij}^* > 0 \\ 0 & \text{if } y_{ij}^* \leq 0 \end{cases} \quad (2)$$

32
33
34
35
36
37
38
39
40 where i indexes the political parties and j the policy issues, and the dependent variable
41
42
43 $Emph_{ij}$ is modelled as censored at 0. $Yield_{ij}$ indicates the computed index of issue yield for
44
45 party i on policy issue j ; Rel_{ij} stands for the relative position of the political party in the
46
47 specific issue; and $Diff_i$ refers to the issue differentiation component of multiparty
48
49 competition. The quantities of interest are β, γ, δ and are expected to be greater than 0. All the
50
51
52
53
54
55
56
57
58
59
60

1
2
3 main terms of the interactions have been included in θX to facilitate readership; y_{ij}^* is the
4
5
6 unobserved uncensored variable; ε_{ij} is a stochastic component clustered within parties.
7
8
9

10 11 12 **Descriptive statistics and empirical results** 13 14

15
16 Before moving to the empirical analysis and hypotheses testing, it is useful to present some
17
18 descriptives related to the positional issues included in the analysis, and to the emphasis
19
20 parties put on them. Table 3 reports, for each party²⁰, the total number of tweets coded as
21
22 positional issues. The table also includes the total number of tweets coded as *valence* issues
23
24 (albeit not analysed here), the total number of tweets related to non-issue content, and finally
25
26 the total number of tweets made during the 21 days of electoral campaign under analysis. As
27
28 can be easily noted, the total number of tweets coded as issues (both positional and valence)
29
30 represents only about a third of the total number of tweets made by the official accounts of
31
32 parties and their leaders during the campaign (942 out of 2832). It follows that about two
33
34 thirds of the tweets (1890) were actually dealing with the campaign dynamics, often
35
36 mentioning other political actors rather than more substantive topics.²¹ The ratio between
37
38 issue and non-issue content is even more unbalanced as concerns the M5S, where as high as
39
40 83.6% of the total tweets are not related to issues. This finding should not come as a surprise
41
42 as it is one of the earliest findings of political communication research, going back to the
43
44 work of the Columbia School: “The most talked-about subject matter during the campaign
45
46 was the campaign itself” (Lazarsfeld, Berelson, & Gaudet, 1944, p. 115).
47
48
49
50
51
52
53
54
55
56
57
58
59
60

Table 3 about here

1
2
3 Focusing on positional issues, a first key finding is the large variability in the absolute
4 number of tweets produced by each party on positional issues: it ranges from only eight
5 tweets produced by the extreme-left party list “Other Europe with Tsipras” (and its leader
6 Nichi Vendola) to 192 produced by Forza Italia and its leader Silvio Berlusconi.
7 Notwithstanding the emphasis pundits and commentators usually put on the ability of Beppe
8 Grillo and his M5S, as well as of Matteo Renzi, on the use of social media for political
9 communication, the campaign of the two main Italian parties, PD and M5S, is characterized
10 by a lower number of tweeted messages compared to other parties and particularly to those
11 belonging to the centre-right bloc: *Forza Italia* and the Northern League together cover 61%
12 of all positional tweets coded. Therefore, Italian parties follow different strategies on Twitter,
13 either selecting a few number of tweets (about one for each day of the campaign) that
14 emphasize the position of the party on a given issue or flooding the potential audience with a
15 massive number of tweets (more than 9 per day as regards *Forza Italia*), often repeating the
16 same tweet more than once during the same day or in following days.²²
17
18
19
20
21
22
23
24
25
26
27
28
29
30
31
32
33

34 But the most important piece of evidence (and a first striking confirmation of the dynamics
35 theorized by the issue yield model) emerges from Table 4, which illustrates the frequency
36 distribution of tweets across issues and parties. Overall, out of the 184 possible cells (23
37 issues for 8 parties) only 53 were actually filled. This means that, on average, each party
38 focuses on only about seven issues during the campaign (from a minimum of 5 for ‘Other
39 Europe with Tsipras’ to a maximum of 9 for *Forza Italia*). Moreover, while some issues are
40 only mentioned by a single party, such as sustainable development (owned by the M5S),
41 others are mentioned by several parties (like immigration or Renzi’s institutional reforms).
42 We have already noted the large variation in the number of tweets made by each party during
43 the campaign. A similar variation occurs as far as issues are concerned: out of the 23 issues
44 selected by the research team as potentially relevant for the campaign, only 16 have actually
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 received attention by parties, while seven have been completely ignored. Moreover, among
4
5 the 16 issues on which parties have put at least some emphasis, we find a large number of
6
7 issues with a few tweets only (11 issues range between 4 and 18 tweets), while six receive
8
9 larger attention, with more than 20 tweets across the 21 days of campaign.
10

11
12 It is worth examining what are the issues that receive most overall attention, although this
13
14 finding is potentially biased by the disproportionate tendency of some parties to tweet much
15
16 more than others. The most important policy areas on which parties focus are immigration,
17
18 Europe, Renzi's institutional reforms and economic redistribution. The most tweeted issue is
19
20 immigration (107 tweets), receiving a large emphasis especially from the two opposition
21
22 parties that share the most negative views on immigrants: the Northern League and Brothers
23
24 of Italy, for which this issue accounts, respectively, for 39 % and 32 % of their positional
25
26 tweets. Not by chance, Northern League and Brothers of Italy are by far the two parties with
27
28 the highest yield on this issue (0.95 and 1 respectively). Considered together, the two issues of
29
30 EU integration and exit from the Euro area are the most salient during the campaign, with 185
31
32 tweets: this finding could be considered surprising, given that one of the assumption of the
33
34 second-order election theory is that the campaign is usually dominated by national issues
35
36 (Reif and Schmitt 1980). However, this is mostly due by the tweet-prolific style of FI and LN.
37
38 In general, parties that have a positive stance towards Europe usually focus on EU integration
39
40 (the overall majority of tweets on this issues come from European Choice that has a very high
41
42 yield on this issue, 0.88), while the issue related to the possible exit from the Euro area is
43
44 owned by the Northern League (80 tweets out of 94) that carried out a heated campaign
45
46 against the single currency. The issue of Renzi's institutional reform is only partially
47
48 exploited by Renzi and the PD (16 % of their tweets are on this issue) but it becomes the main
49
50 issue – negatively – emphasized by the M5S. On the contrary, Renzi's party choses to focus
51
52 on the reduction of income inequality (42 % of its tweets are on this issue) given the fiscal
53
54
55
56
57
58
59
60

1
2
3 bonus of 80 euro provided by the government to low-income people just before the start of the
4
5 electoral campaign. Another very important issue is related to the controversy emerged within
6
7 the center-right bloc about the supposed “betrayal” of Alfano (the leader of New Center-right,
8
9 NCD) against Berlusconi: not surprisingly, the only parties to mention this issue are the two
10
11 ones involved in the controversy, namely *Forza Italia* (28 tweets) and NCD (29 tweets).
12
13 Furthermore, note that 72 tweets have been classified as “other issues”, since they deal with
14
15 positional issues falling outside the 23 surveyed ones²³.
16
17
18
19

20
21 Table 4 about here
22
23
24

25 Exploring the data, we have already pointed out a number of relevant empirical findings,
26
27 and most importantly, we have implicitly assessed at face validity our measure of Twitter
28
29 emphasis. We can finally proceed with the empirical testing of the three hypotheses presented
30
31 in the second section. In particular, we want to test whether the emphasis that parties place on
32
33 the policy issues is predicted by issue yield, and secondly whether the influence of other
34
35 parties’ strategies can be effectively modelled through our two indicators related to multi-
36
37 party competition.
38
39
40

41 42 Testing the hypotheses 43

44 In Table 5, we present estimations of tobit models of Twitter emphasis, according to three
45
46 different empirical specifications. In model (1), we model Twitter emphasis on issue yield; in
47
48 model (2), we add the party’s issue yield *relative position* on that issue; finally, in model (3)
49
50 we estimate the full theoretical model, including issue yield *differentiation* on that issue. The
51
52 results are striking. The coefficient for issue yield is positive and statistically significant: as a
53
54 result, Hypothesis 1 is confirmed: issue yield (measured before the campaign) is a predictor of
55
56
57
58
59
60

1
2
3 Twitter emphasis of specific issues during the campaign, with a remarkable and statistically
4 significant effect (and with a pseudo- R^2 of 0.09)²⁴. The second model's specification adds the
5 relative component. The presence of a positive and significant interaction between issue yield
6 and the *Rel* variable (relative position) confirms Hypothesis 2. The better the party ranking on
7 the issue, the stronger the effect of issue yield. Such result (even clearer from the marginal
8 plots reported below in Figure 1) in fact shows that issue yield has no effect on tweets'
9 proportions for those issues where the party – compared to other parties – has the lowest level
10 of issue yield. The result is reasonable, because when a party has the lowest yield on an issue
11 compared to other parties, then emphasizing it (regardless of the low or high value of yield)
12 will be counterproductive, ending up favouring a competitor. But for higher values of the *Rel*
13 variable (relative position) the effect of issue yield becomes positive and significant.
14 Moreover, when adding this component of multiparty competition the pseudo R^2 increases up
15 to 0.14. These findings are a clear confirmation for Hypothesis 2.
16
17
18
19
20
21
22
23
24
25
26
27
28
29
30
31
32
33
34

35 Table 5 about here
36
37
38
39

40 Finally, the main specification includes both components of multiparty competition. Here,
41 again, the presence of a positive and significant interaction between issue yield and our
42 differentiation index clearly confirms Hypothesis 3: issue yield dynamics are effective for
43 issues where parties are clearly differentiated.²⁵ However, it has to be considered that models
44 are nonlinear. Therefore, we can only have indications regarding the presence and the sign of
45 the relationships, because coefficients represent the marginal effect on the latent uncensored
46 dependent variable ($\beta = \frac{\partial E[y^*|x]}{\partial x}$). Furthermore, it is opportune to estimate the effect of the
47 covariates on the censored distribution: $\beta \cdot \Phi(x'\beta) = \frac{\partial E[y|x, y>0]}{\partial x}$. In this case, the marginal
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 effect of issue yield on the number of tweets for a certain issue ranges from -0.12 when issue
4 yield is equal to its minimum ($Yield = 0.294$) and +0.14, for the maximum level of
5
6
7
8 $Yield = 1$. To better assess the magnitude of the relations, especially because the three

On the left pane, the figure shows that the effect of issue yield on Twitter communication is conditional on the parties being enough differentiated on a given issue. Specifically, issue yield presents positive and significant effects only for levels of issue differentiation above 0.45 (approximately). This for example corresponds to an issue where the top party on that issue has a yield of 0.90 and the worst party has a yield of 0.45. Thus, parties systematically tend to emphasize a topic only insofar as issue opportunities are clearly differentiated among parties on that issue, so that the advantaged parties are rather certain about the potential electoral return. Otherwise, parties refrain from emphasizing issues where – regardless of the yield level – other parties have similar yields, thus with the risk of being benefited by the party's emphasis. This result provides supporting evidence for Hypothesis 3: issue yield dynamics are relevant on issues where parties' yields are sufficiently differentiated.

Figure 1 about here

The graph on the right pane finally shows how the effect of issue yield on Twitter issue emphasis increases for those parties with the highest issue yield ranking on that topic. Our interpretation of this finding is that political parties are only sensitive to issue yield for those issues where they rank highest (this corresponds to a relative position of 0.8 or higher, in fact mostly corresponding to ranking first or second on the issue); otherwise they become indifferent to issue yield, as an emphasis could advantage some other party.²⁶

1
2
3 Finally, the aforementioned effects of issue yield (with the moderating effect of relative
4 position and differentiation) are perhaps best exemplified by looking at the predicted
5 probabilities that a party will tweet at least once on a specific issue, based on its issue yield
6 configuration. When computing such probabilities for different scenarios,²⁷ one understands
7 the importance of issue yield. For example, comparing two issues with low (< 0.4) and high
8 (> 0.9) yield, probability of nonzero party twitting on the issues goes from 18 % to 58 %. For
9 issues with average yield (0.55 to 0.85, corresponding to the mean plus or minus one standard
10 deviation), a party ranking first will have a twitting probability of 41 %, while a party ranking
11 last will have a probability of 14 %. Finally, for issues with high yield (> 0.9), the probability
12 is 38 % when party differentiation is low (issue yield for all parties in a range of 0.25 or
13 lower), while it jumps to 78 % when party differentiation is high (issue yields in a range of
14 0.64 or larger).

23
24
25 Overall, we find that issue yield theory is clearly confirmed by this empirical exercise, and
26 with an important explanatory contribution provided by our two innovative measures of
27 multi-party competition dynamics.
28

29 30 31 32 33 34 35 36 37 **Conclusions**

38
39
40 The main goal of this paper was the theoretical elaboration of the issue yield model for multi-
41 party competition contexts, along with the introduction of a novel research design, aimed at
42 testing the issue yield model by overcoming some of the limitations of previous studies. In
43 particular, the crucial innovation was twofold: the introduction of a framework for multi-party
44 competition; and the adoption of Twitter content for measuring the outcome, i.e. the issue
45 emphasis employed by different parties on different issues. As for the first aspect, our
46 discussion and operationalization of multi-party dynamics, leading to the introduction of the
47 concepts of *issue yield relative position* and *issue yield differentiation*, appear valid and
48

1
2
3 empirically supported. Indeed, the performance of the model significantly improves when
4 specifically calibrated by taking into account the complex dynamics of multi-party
5 competition, as expressed by our newly introduced measures.
6
7
8

9
10 Secondly, results confirm the validity of the research design, in two regards. First, issue
11 yield dynamics are clearly relevant even in Twitter communication: issue yield is a significant
12 predictor of Twitter issue emphasis, also providing a non-trivial amount of variance
13 explained. Also, the clear asymmetries between parties in the emphasis dedicated to different
14 issues testify the clearly strategic dynamics that characterize party communication on Twitter.
15
16 Additionally, a very important finding concerns the very possibility of developing a coding
17 scheme for matching Twitter content to positional issue statements. Results are impressively
18 positive: despite the complexity of the scheme, independent coders with no particular
19 previous training were able to reach extremely high levels of inter-coder reliability. This
20 yields a very optimistic scenario for the replication of this design in new contexts, and
21 suggests the soundness of this research design.

33

34 However, we argue that the contribution of this paper is of mostly substantive interest, in
35 times of an increasing presence of parties that challenge existing party system structures by
36 relying on specific issue packages. Building on the issue yield model (which adopts a
37 dynamic and strategic view of the issue agenda, compared to the static view of previous
38 frameworks), our contribution not only introduces a realistic model of multi-party dynamics,
39 but also develops an empirical research framework which is able – unlike previous
40 applications of the issue yield model – to effectively capture even the short-term dynamics of
41 issue competition (and perhaps even the presence of opportunities not yet exploited by any
42 party). As a result, we argue that the future replication of our design across more elections and
43 countries could provide breakthrough insights into the innovative issue competition strategies

adopted by both mainstream and challenger parties. This in turn could lead to a realistic view of how party competition is evolving in these turbulent times.

Notes

¹ In the example reported by Stokes (1963), Eisenhower in 1952 decided to campaign on “Korea, Communism, and Corruption” – where he could claim far superior credibility – while avoiding a spatial, Downsian strategy on the left-right dimension. Given the overwhelming support of Americans for New Deal policies, this latter would have likely resulted in defeat.

² Such model would of course only cover the *strategic* component of the party system agenda, still leaving a role for *systemic salience* (Steenbergen & Scott, 2004; Wagner, 2012).

³ Recent applications of issue ownership theory have mostly adopted survey-based, more dynamic measures of issue ownership, usually through items capturing party competence on a list of shared goals (Walgrave, Lefevre, & Tresch, 2012, pp. 781–84). However, these strategies still assume an underlying *valence* logic which hardly generalizes to positional issues (especially relevant in multi-party systems). This potential limitation is somehow also present in innovative approaches such as *associative issue ownership* (ibidem).

⁴ The authors explicitly define issue entrepreneurship as “the ... mobilization of a previously ignored and not divisive issue [on] ... a policy position ... substantially different from the status quo position of the mainstream” (Hobolt & De Vries, 2015, p. 1163).

⁵ Departing from the Downsian model, the issue yield model assumes that parties will mostly attempt *not to change* their policy positions, as this move is often costly and difficult. The model instead posits that a party disadvantaged on some issue will downplay its importance and turn to other issues where it enjoys a more favorable position.

⁶ Party positions are operationalized in dichotomous form (*for* or *against* a given policy).

⁷ Identified through vote intention.

⁸ The index is calculated according to a non-linear expression. Let p be the percentage of respondents supporting a party; i the percentage approving a policy statement, f the percentage jointly supporting the party and approving the statement; then the issue yield index is expressed by

$$yield = \frac{f - ip}{p(1 - p)} + \frac{i - p}{1 - p}$$
 (De Sio and Weber 2014, 876-878).

⁹ Our choice of selecting an EP election is not specifically related to EU politics, but relying on the approach of considering EP elections as “windows into national political processes” (Van der Eijk & Franklin, 1996; Brug, Eijk, & Franklin, 2007; De Sio & Franklin, 2012). Based on the consensus over EP elections as “second-order” elections, we deem that this selection does not introduce significant biases in terms of testing our multi-party model, as EP campaigns tend to be dominated by domestic issues (as was the case for Italy in 2014: see De Sio, Emanuele, & Maggini, 2014).

¹⁰ The questionnaire also included credibility items for 17 valence issues, not analysed here, but included in the Twitter coding scheme.

¹¹ CAWI fieldwork took place between April 29 and May 9, 2016, on a sample of the adult population resident in Italy (response rate was 25.9%). Respondents were extracted – according to a quota sampling by sex, age and geographical area – from a Web respondent community. Results reported here (except for the final models) were then weighted by stratification variables, plus level of education, political interest and past party vote recall. As suggested by Pasek (2016), an online survey relying on a non-probability sample may provide imperfect estimates of the frequencies of politically relevant variables. This is confirmed by e.g. frequency distributions for political interest in our sample with a well-known and widely-used probability sample, the 2013 CAPI survey from the ITANES (Italian National Election Studies). The two distributions show significant differences, with very interested and fairly interested representing 75% of respondents in our survey vs. 37% according to ITANES, and a reported turnout of 85.5% vs. the actual 58.7%. However, such large differences in political interest do not translate in equally large differences in the main quantities of interest. When comparing unweighted with weighted data (with our weight also including political interest), support for specific policies (both at large and within each party) only differs by few percentage points, so that a final robustness check we performed (replicating our final models on both weighted and unweighted data) yields fully equivalent results (available on request).

¹² The total number of observations for issue yield is 368, since each issue has two sides (*pro* or *anti*). The final number of observations is 184 (368/2) because we assume the optimal side is chosen (the one with the highest yield).

¹³ We coded tweets from official accounts of the following parties and leaders: Democratic Party (PD), Five Star Movement (M5S), Forza Italia (FI), Northern League (LN), New Center-right (NCD), Other Europe with Tsipras (TSIPRAS) and European Choice (SE); and from official accounts of the following leaders: Matteo Renzi (PD), Beppe Grillo (M5S), Silvio Berlusconi (FI), Giorgia Meloni (Brothers of Italy, FDI), Angelino Alfano (NCD), Nichi Vendola (TSIPRAS) and Andrea Romano (SE). A party account did not exist for FDI, while a leader account did not exist for Matteo Salvini (LN). In both cases, we coded party communication from the other available account (Giorgia Meloni and Northern League).

¹⁴ Twitter content was collected between April 14 and May 4, covering between 6 and 3 weeks before the vote.

¹⁵ Fleiss (1981)'s guidelines to interpret the meaning of the kappa statistic consider values over 0.75 as excellent. Kappa values were calculated on a 40-issue coding scheme that included both the 23 positional issues and the 17 valence issues (not analyzed here).

¹⁶ Such rescaling to 0-1 eliminates between-issue differences in issue yield differentiation, which are separately captured by the previous index. As a result, we can separately assess these two distinct conceptual aspects.

¹⁷ While developing our multi-party extension of the issue yield model, we also explored alternative explanations, with special regard to the relevance of *systemic salience* (Steenbergen & Scott, 2004; Kaplan, Park, & Ridout, 2006; Wagner, 2012) and of a more classic operationalization of *issue ownership*. Results of these

explorations, which confirm the validity of our model, are reported in the Appendix, and briefly mentioned below in terms of robustness checks.

¹⁸ This is not surprising, and indeed a confirmation that parties tend to concentrate their emphasis on a relatively small number of issues among all the potential issues available.

¹⁹ Another possibility is to fit a linear model on the logit transformation of the dependent variable (Papke & Wooldridge, 1996). However, this would exclude 0s and 1s, which would require a separate treatment. This problem appears relevant, as 0s are the mode of the distribution. For the same reason, tweets' proportions cannot be modeled through a beta distribution.

²⁰ Each row represents the sum of the official account of the party and that of the respective party leader.

²¹ In any case, coders were clearly instructed to code as issue-related all tweets that presented issue content, regardless of the presence of references to other actors.

²² In a way, the relatively sparse communication style of some parties is a confirmation of the press release assumption: under strong media attention, even a single daily tweet will have a very large media impact.

²³ Indeed, note that all the 72 tweets classified as "other issues" were about the classic taxes/public services trade-off, which – in this particular framing – we did not include in our classification scheme. However, this represents a confirmation of the overall validity of our ex-ante issue selection, given that only one relevant issue was not included in the scheme.

²⁴ We performed additional robustness checks. In particular, we controlled for systemic issue salience by relying on a convenience operationalization first used by Bartels (1986), based on the number of missing responses on issue stances (capturing the inverse of issue salience). The results (Table A2 in the Appendix) are reassuring, showing a positive and significant effect of systemic issue salience but still leaving the results of our model fundamentally unchanged. We also controlled for the effect of issue ownership by introducing a dichotomous variable where issues that are unambiguously owned by a given party are coded 1, and all the remaining issues are coded 0 (party-issue pairings available on request). The effect of issue yield remains significant even when we control for issue ownership (Table A3 in the Appendix). Moreover, we performed a leave-one-out test by re-running the analyses reported in Table 5 excluding one party at a time and one issue at a time (for our 23 positional issues and 8 parties). The results are substantially identical to those reported in Table 5 (results available upon request).

²⁵ The results appear clearly robust, as they hold even if we model the issue emphasis with simple OLS regression, or even with a mixture of a beta distribution (modeling the internal values) and a Bernoulli distribution (to inflate the 0s). This latter specification would correspond to a more articulated decision process (Ospina & Ferrari, 2012), separating *which* issues to emphasize from *how much* to emphasize them.

²⁶ The presence of apparently negative effects of issue yield for extremely low values of *Rel* emerges from issues of parametric extrapolation of the simplified multiplicative interaction (such effects mostly disappear when modelling the interaction through dummies for different levels of *Rel*), combined with distributional considerations arising from the correlation between the two variables that are interacted (yield and *Rel*). In particular, combinations of very high yield with very low values of *Rel* would only materialize in presence of almost unanimous issues, where issue yield values would lose most of their meaning.

²⁷ We computed the probabilities that tweets' proportions for each party-issue pair are larger than zero, by fixing values of issue yield, differentiation and relative support at specific, meaningful values.

Table 1. Risks and opportunities for party competition related to several policy issues, according to the issue yield model (PD, M5S, FI and LN in 2014; source: original data collection).

Policy	Agreement at large	Agreement within the party				Issue yield							
		PD	M5S	FI	LN	PD		M5S		FI		LN	
						Pro	Anti	Pro	Anti	Pro	Anti	Pro	Anti
Reduce spending for F-35 fighters	88	92	94	70	83	0.88	-0.48	0.93	-0.13	0.68	0.24	0.82	0.14
Change towards a sustainable model of development	87	93	94	81	79	0.89	-0.49	0.93	-0.13	0.79	0.13	0.79	0.18
Reduce income inequality	84	91	91	76	74	0.85	-0.45	0.89	-0.09	0.74	0.19	0.73	0.23
Tougher attitude with India on the Enrica Lexie case	80	81	78	90	98	0.69	-0.29	0.73	0.07	0.90	0.03	0.98	-0.02
More restrictive immigration laws	78	57	79	90	95	0.32	0.08	0.75	0.06	0.89	0.04	0.95	0.02
Reduce taxes before fighting tax evasion	75	56	78	88	78	0.29	0.11	0.74	0.06	0.87	0.05	0.77	0.20
Italian citizenship should be given to children born in Italy	74	89	72	57	36	0.82	-0.42	0.67	0.14	0.54	0.38	0.34	0.62
Foreign companies selling services via the Internet should be taxed here	74	84	70	67	74	0.75	-0.35	0.64	0.16	0.64	0.28	0.73	0.23
EU integration is a good thing	71	91	70	60	41	0.85	-0.45	0.64	0.16	0.57	0.35	0.39	0.57
Welfare chauvinism	70	44	71	77	93	0.10	0.30	0.65	0.15	0.76	0.17	0.93	0.03
Heterologous insemination should be allowed	68	77	77	72	59	0.63	-0.23	0.73	0.07	0.70	0.22	0.57	0.39
Prostitution should be legalized	64	67	79	76	83	0.46	-0.06	0.75	0.06	0.74	0.19	0.82	0.14
A universal unemployment check should be introduced	59	62	74	60	43	0.39	0.01	0.68	0.12	0.57	0.35	0.41	0.55
Introduce civil partnerships, even for gay couples	58	73	66	45	38	0.57	-0.17	0.59	0.21	0.41	0.51	0.36	0.61
Reduce the power of the judiciary	49	27	40	72	81	-0.18	0.58	0.28	0.52	0.70	0.22	0.80	0.16
Companies should have more freedom to hire and fire	44	36	37	65	69	-0.03	0.43	0.25	0.55	0.63	0.30	0.68	0.28
Founding NCD, Alfano betrayed Berlusconi	40	22	40	77	66	-0.24	0.64	0.28	0.52	0.76	0.17	0.64	0.32
To fight tax evasion, cash transaction limits should be lowered	35	59	40	29	24	0.35	0.05	0.28	0.53	0.23	0.69	0.21	0.75
Soft drugs should be legalized	31	43	53	23	24	0.09	0.31	0.44	0.37	0.18	0.75	0.21	0.75
Renzi's institutional reforms reduce democratic participation	31	15	37	44	43	-0.36	0.76	0.24	0.56	0.40	0.52	0.41	0.55
Italy should leave the Euro	29	6	40	40	76	-0.50	0.90	0.28	0.53	0.35	0.57	0.75	0.21
Italy should be split into macro-regions, with right to secession	26	10	24	47	69	-0.44	0.84	0.09	0.72	0.43	0.49	0.68	0.28
Abortion should be made more difficult	25	19	21	35	36	-0.29	0.69	0.06	0.75	0.30	0.63	0.34	0.62

Table 2. Results of the classification of tweets, by two independent coders.

Agreement	Expected agreement	Kappa	Standard error	Z	P-value
81.75%	7.99%	0.80	0.01	73.79	0.0000

Table 3. Counts of tweeted messages: positional, valence and non-issue messages.

Party	Positional issues		Valence Issues		Non-issue content		Total	
	N	%	N	%	N	%	N	%
Pd	19	16.8	24	21.2	70	61.9	113	100
M5S	32	7.8	35	8.6	341	83.6	408	100
Fi	192	14.7	202	15.5	913	69.9	1307	100
Ln	160	33.1	27	5.6	296	61.3	483	100
Se	79	48.5	21	12.9	63	38.7	163	100
FdI	25	28.1	4	4.5	60	67.4	89	100
Ncd	59	29.2	44	21.8	99	49.0	202	100
Tsipras	8	11.9	11	16.4	48	71.6	67	100
<i>Total</i>	574	20.3	368	13.0	1890	66.7	2832	100

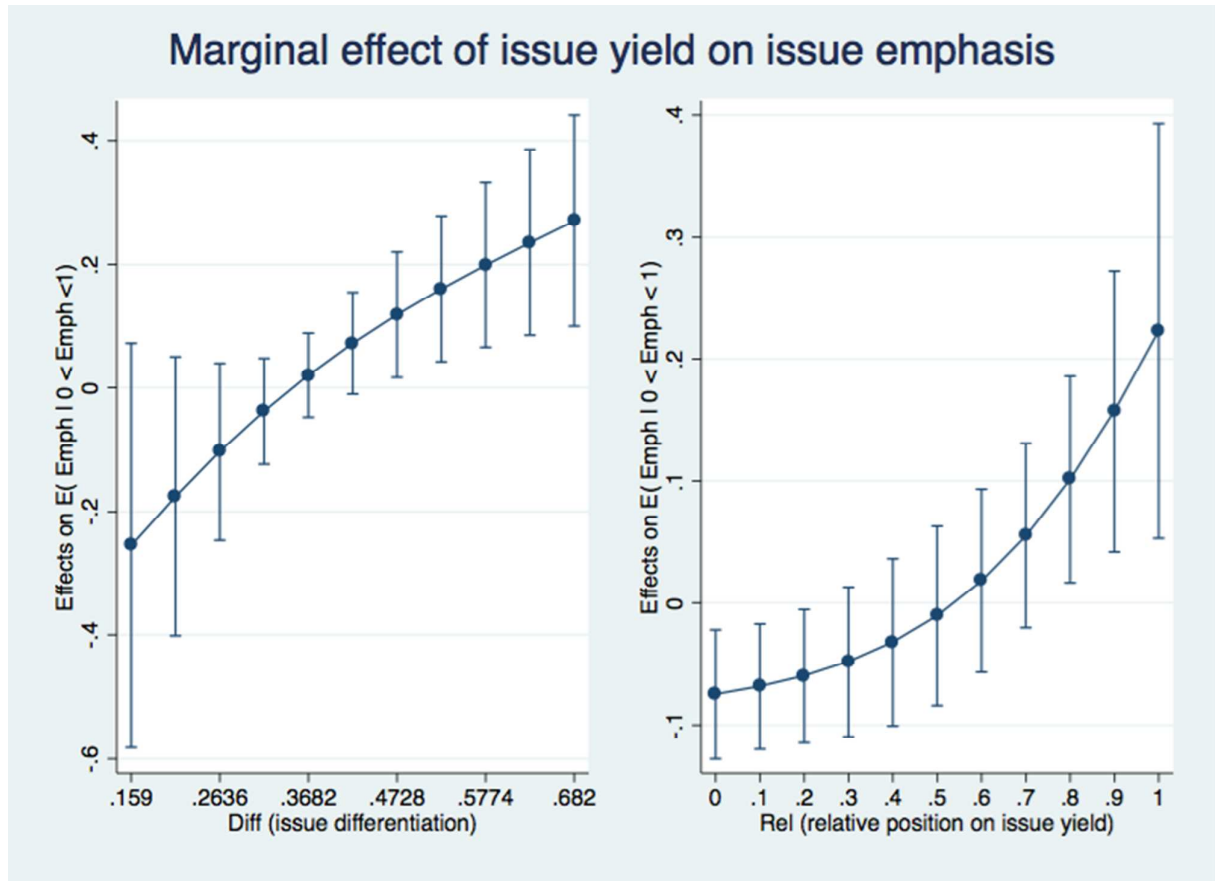

Table 4. Frequency distribution of tweets across positional issues, by party.

Policy	Party							N	
	Pd	M5s	Fi	Ln	Ncd	Fdi	Tsipras		Se
Change towards a sustainable model of development		8							8
Reduce spending for F-35		5					2		7
Reduce income inequality	8	2	6		4	1			21
Tougher attitude against India on the <i>Enrica Lexie</i> case	1			2		2			5
Foreign companies selling services via internet should be taxed									0
Italian citizenship should be given to children born in Italy									0
EU integration is a good thing	1		31	2	1		2	54	91
Heterologous fecondation should be allowed									0
Prostitution should be legalized									0
Immigration laws should be more restrictive			22	63	12	8	1	1	107
Before fighting tax evasion, taxes should be reduced	1		12						13
Civil partnerships									0
A universal unemployment check should be introduced		4							4
Welfare chauvinism				4		4			8
To fight tax evasion, cash limit should be lowered									0
Soft drugs should be legalized				2		3		3	8
Reduce the power of the judiciary	1		5	2					8
Companies should have more freedom to hire and fire		1	5		5		2	5	18
Founding NCD, Alfano betrayed Berlusconi			28		29				57
Renzi's institutional reforms reduce democratic participation	3	12	24	3	2	3		2	49
Pro life						4			4
Italy should leave the Euro			2	80			1	11	94
Italy should be split into macro-regions									0
Other issues	4		57	2	6			3	72
Total	19	32	192	160	59	25	8	79	574

Table 5. Regression analysis of Twitter emphasis.

	Model (1)	Model (2)	Model (3)
<i>Yield</i>	0.55*** (4.63)	-0.34 (-1.18)	-1.80** (-3.14)
<i>Rel</i>	▪	-0.57 (-1.81)	-0.65* (-2.42)
<i>Yield</i> × <i>Rel</i>	▪	1.05* (2.34)	1.26** (2.69)
<i>Diff</i>	▪	▪	-2.33* (-2.59)
<i>Yield</i> × <i>Diff</i>	▪	▪	2.90** (2.88)
Constant	-0.54*** (-5.31)	-0.04 (-0.27)	1.06* (2.24)
Observations	184	184	184
Pseudo- R^2	.09	.14	.19

Note: table entries represent coefficients for the Tobit regression of issue emphasis on the hypothesized predictors (estimation based on robust standard errors, with observations clustered by party). The dependent variable is censored at 0. T-statistics reported in parentheses. * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$.

Note: the two charts represent graphically the Tobit model (3) reported Table 5. The left pane represents the conditional effect of issue yield on Twitter emphasis for varying values of issue differentiation. The right pane represents the same effects for varying values of the relative position of the parties with respect to the issues. Only the values for the subpopulation of issues with at least one tweet $E(Emph_{ij} | Emph_{ij} > 0)$ are reported.

Vertical bars represent 95% confidence interval.

Figure 1. Multiparty dynamics: marginal effect of issue yield on issue emphasis

Appendix

Table A1. Potentially relevant issues (with question wordings) for the 2014 EP campaign in Italy, as selected by the research team

Type	Keyword	Question
Positional	Model of development	The actual model of development should be changed to get it more sustainable from an environmental and social viewpoint
Positional	Military spending	Italy should reduce spending for the F-35 fighter-bombers
Positional	Income inequality	Income inequalities should be reduced
Positional	Enrica Lexie case	The government should have a tougher attitude against India about the Enrica Lexie case
Positional	Webtax	Foreign companies selling services via internet in Italy should be taxed by the Italian tax authorities
Positional	Citizenship	Italian citizenship should be given to children born in Italy from legally resident foreign parents
Positional	EU integration	EU integration is a good thing
Positional	Heterologous insemination	Heterologous insemination should be allowed in Italy
Positional	Prostitution	Prostitution should be legalized
Positional	Immigration	Immigration laws should be more restrictive
Positional	Taxes	Before fighting tax evasion, taxes should be reduced
Positional	Civil partnerships	Civil partnerships between same sex should be recognized
Positional	Unemployment check	A universal unemployment check should be introduced
Positional	Welfare chauvinism	Social services should protect above all Italians, and only later, possibly immigrants.
Positional	Cash limit	To fight tax evasion, cash limit should be lowered
Positional	Soft drugs	Soft drugs should be legalized
Positional	Judiciary	The power of the judiciary should be reduced
Positional	Freedom of enterprise	Companies should have more freedom to hire and fire
Positional	Alfano	Founding NCD, Alfano betrayed Berlusconi
Positional	Institutional reforms	Renzi's government institutional reforms could reduce the opportunities for democratic participation
Positional	Abortion	Abortion should be made more difficult
Positional	Euro	Italy should leave the Euro
Positional	Secession	Italy should be split into macro-regions provided with the right of secession
Valence	Costs of politics	Which party is more credible to reduce the costs of politics
Valence	Growth vs. austerity	Which party is more credible to push Europe to favor economic growth, instead of austerity, on public finance
Valence	Jobs	Which party is more credible to create new jobs
Valence	Italy's interests	Which party is more credible to enforce Italy's interests in Europe
Valence	Pay debts	Which party is more credible to quickly pay State's debt to creditor businesses
Valence	Boost economy	Which party is more credible to boost Italian economy
Valence	Political class	Which party is more credible to renew the political class
Valence	Crime	Which party is more credible to make citizens safer from crime
Valence	Politics vs. technicians	Which party is more credible to put back the decisions taken in Europe in the hands of politics, instead in those of non-elected technicians
Valence	Gender equality	Which party is more credible to provide more space to women in politics and society
Valence	Bureaucracy	Which party is more credible to simplify the bureaucracy
Valence	Justice	Which party is more credible to make justice more efficient and faster
Valence	Mafia	Which party is more credible to fight organized crime
Valence	Access to credit	Which party is more credible to facilitate access to credit for citizens and businesses
Valence	School	Which party is more credible to relaunch the Italian school
Valence	Pollution	Which party is more credible to fight pollution and the disruption of the territory
Valence	Art and culture	Which party is more credible to protect and promote the cultural and artistic heritage

Table A2. Regression analysis of Twitter emphasis controlling for systemic issue salience

	Model 1	Model 2	Model 3
<i>Yield</i>	0.55 ^{***} (3.88)	-0.39 (-1.41)	-1.84 ^{***} (-3.36)
<i>Rel</i>		-0.46 (-1.49)	-0.54 (-1.84)
<i>Yield</i> × <i>Rel</i>		0.97 [*] (2.11)	1.17 [*] (2.35)
<i>Diff</i>			-2.23 [*] (-2.52)
<i>Yield</i> × <i>Diff</i>			2.88 ^{**} (2.92)
<i>Systemic salience</i>	0.24 ^{**} (2.73)	0.25 ^{**} (3.18)	0.25 [*] (2.48)
Constant	-0.64 ^{***} (-5.15)	-0.14 (-0.96)	0.93 [*] (2.03)
<i>N</i>	184	184	184
Pseudo- <i>R</i> ²	0.13	0.186	0.235

Note: table entries represent coefficients for the Tobit regression of issue emphasis on the hypothesized predictors (estimation based on robust standard errors, with observations clustered by party). The dependent variable is censored at 0. T-statistics reported in parentheses. * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$.

Table A3. Regression analysis of Twitter emphasis controlling for issue ownership

	Model 1	Model 2	Model 3	Model 4
<i>Yield</i>		0.46*** (3.71)	-0.23 (-0.97)	-1.52** (-2.75)
<i>Rel</i>			-0.55 (-1.90)	-0.62* (-2.24)
<i>Yield × Rel</i>			0.93* (2.26)	1.11* (2.44)
<i>Diff</i>				-2.04* (-2.27)
<i>Yield × Diff</i>				2.57* (2.56)
<i>Ownership</i>	0.34** (2.95)	0.29* (2.54)	0.26* (2.26)	0.24 (1.87)
<i>Constant</i>	-0.16*** (-6.08)	-0.48*** (-4.65)	-0.08 (-0.58)	0.88 (1.91)
<i>N</i>	184	184	184	184
Pseudo- R^2	0.096	0.167	0.206	0.249

Note: table entries represent coefficients for the Tobit regression of issue emphasis on the hypothesized predictors (estimation based on robust standard errors, with observations clustered by party). The dependent variable is censored at 0. T-statistics reported in parentheses. * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$.
